(57) **ABSTRACT**

An interconnect structure and a method of forming an interconnect structure are provided. The interconnect structure is formed over a carrier substrate, upon which a die may also be attached. Upon removal of the carrier substrate and singulation, a first package is formed. A second package may be attached to the first package, wherein the second package may be electrically coupled to through vias formed in the first package.

INTERCONNECT STRUCTURE FOR PACKAGE-ON-PACKAGE DEVICES

This application is a continuation of U.S. patent application Ser. No. 15/283,118, filed on Sep. 30, 2016, entitled “Interconnect Structure for Package-On-Package Devices and a Method of Fabricating,” which is a continuation of U.S. patent application Ser. No. 14/720,154, filed on May 22, 2015, entitled “Interconnect Structure For Package-On-Package Devices And A Method of Fabricating,” now U.S. Pat. No. 9,460,987, which is a continuation of U.S. patent application Ser. No. 13/787,547, filed on Mar. 6, 2013, entitled “Method of Fabricating Interconnect Structure for Package-on-Package Devices,” now U.S. Pat. No. 9,048,222, which applications are hereby incorporated herein by reference in their entirety.

BACKGROUND

Since the invention of integrated circuits, the semiconductor industry has experienced continuous rapid growth due to constant improvements in the integration density of various electronic components (i.e., transistors, diodes, resistors, capacitors, etc.). For the most part, these improvements in integration density have come from repeated reductions in minimum feature size, allowing more components to be integrated into a given chip area.

These integration improvements are essentially two-dimensional (2D) in nature, in that the volume occupied by the integrated components is essentially on the surface of the semiconductor wafer. Although dramatic improvements in lithography have resulted in considerable improvements in 2D integrated circuit formation, there are physical limitations to the density that can be achieved in two dimensions. One of these limitations is the minimum size needed to make these components. Also, when more devices are put into one chip, more complex designs are required. An additional limitation comes from the significant increase in the number and length of interconnections between devices as the number of devices increases. When the number and length of interconnections increase, both circuit RC delay and power consumption increase.

Three-dimensional integrated circuits (3DICs) were thus formed, wherein two dies or packages may be stacked, with through-silicon vias (TSVs) formed in one of the dies or packages to connect the other die to another substrate. Package on Package (PoP) is becoming an increasingly popular integrated circuit packaging technique because it allows for higher density electronics.

BRIEF DESCRIPTION OF THE DRAWINGS

For a more complete understanding of the embodiments, and the advantages thereof, reference is now made to the following descriptions taken in conjunction with the accompanying drawings, in which:

FIGS. 1-11 illustrate various intermediate stages in the manufacturing of a package in accordance with an embodiment;

FIGS. 12-18 illustrate various intermediate stages in the manufacturing of a package in accordance with another embodiment;

FIGS. 19-22 illustrate various intermediate stages in the manufacturing of a package in accordance with yet another embodiment;

FIG. 23 illustrate a package in accordance with yet still another embodiment;

FIG. 24 is a flow chart of a method that may be used in accordance with some embodiments;

FIG. 25 is a flow chart of a method that may be used in accordance with some other embodiments; and

FIG. 26 is a flow chart of a method that may be used in accordance with some other embodiments.

DETAILED DESCRIPTION OF ILLUSTRATIVE EMBODIMENTS

The making and using of the embodiments of the disclosure are discussed in detail below. It should be appreciated, however, that the embodiments provide many applicable inventive concepts that can be embodied in a wide variety of specific contexts. The specific embodiments discussed are merely illustrative and do not limit the scope of the disclosure.

A novel three-dimensional integrated circuit (3DIC) and the method of forming the same are provided. The intermediate stages of manufacturing an embodiment are illustrated. The variations of the embodiment are discussed. Throughout the various views and illustrative embodiments, like reference numbers are used to designate like elements.

FIGS. 1-11 illustrate various intermediate stages of manufacturing in which a package-on-package (PoP) structure is fabricated. In this embodiment a protective layer (e.g., a PBO layer) is formed over an integrated circuit die in a lower package, wherein the protective layer extends over an upper surface of the lower package. Openings are formed in the protective layer to allow electrical connections to be formed.

Referring first to FIG. 1, there is shown a carrier substrate 102 having an adhesive layer 104 and a protective layer 106 formed thereon. Generally, the carrier substrate 102 provides temporary mechanical and structural support during subsequent processing steps, such as those described in greater detail below. The carrier substrate 102 may comprise, for example, glass, silicon oxide, aluminum oxide, a combination thereof, and/or the like. The adhesive layer 104 may be any suitable adhesive, such as ultraviolet (UV) glue, which loses its adhesive property when exposed to UV lights, and may be applied via lamination, spin coating, or other suitable techniques. Other types of adhesives may also be used, such as adhesives that lose some adhesive properties when exposed to heat, which may be generated using UV lights or laser.

The protective layer 106 is formed over the adhesive layer 104. As explained in greater detail below, a backside of an integrated circuit die will be placed over the protective layer 106. The protective layer 106 will provide structural support for bonding and help reduce die shift and ball cracking issues. The protective layer 106 also protects the adhesive layer 104 during subsequent processing. It has been found that portions of the adhesive layer 104 may be removed during subsequent processing steps, and that the residue from the adhesive layer 104 may adversely affect subsequent processing steps, including poor chip placement. The protective layer 106 may be formed of, for example, a polybenzoxazole (PBO), polyimide, a solder resist, an epoxy with filler base material, such as LC tape, a die attach film (DAF), a polymer-based material, combinations thereof, or the like, to a thickness from about 1 μm to about 40 μm . Protective layers formed of these materials and thicknesses help control warpage, which in turn reduces poor jointing during die assembly.

FIG. 2 illustrates a seed layer 208 deposited over the surface of the protective layer 106. The seed layer 208 is a

thin layer of a conductive material that aids in the formation of a thicker layer during subsequent processing steps. In an embodiment, the seed layer **208** is formed by depositing a thin conductive layer, such as one or more thin layers of Ti, Cu, Ta, TiN, TaN, combinations thereof, or the like, using CVD or PVD techniques.

Thereafter, as illustrated in FIG. 3, a patterned mask **310** is formed and patterned over the seed layer **208** in accordance with an embodiment. The patterned mask **310** defines the shape of subsequently formed through vias through a molding compound, thereby providing an electrical connection from a first side of a package to a second side of a package. The patterned mask **310** may be a patterned photoresist mask, hard mask, a combination thereof, or the like.

FIG. 4 illustrates the formation of through vias **412** in accordance with an embodiment. The through vias **412** may be formed of any suitable conductive material, including Cu, Ni, Pt, Al, lead-free solder (e.g., SnAg, SnCu, SnAgCu), combinations thereof, or the like, and may be formed through any number of suitable techniques, including electroplating, physical vapor deposition (PVD), chemical vapor deposition (CVD), electrochemical deposition (ECD), molecular beam epitaxy (MBE), atomic layer deposition (ALD), and the like. It should be noted that in some embodiments, such as those that deposit a conformal layer over the entire surface of the wafer (e.g., PVD and CVD), it may be desirable to perform an etching or planarization process (e.g., a chemical mechanical polishing (CMP)) to remove excess conductive material from the surface of the patterned mask **310**.

FIG. 5 illustrates removal of the patterned mask **310** in accordance with an embodiment. In embodiments in which the patterned mask **310** is formed from photoresist materials, the photoresist may be stripped by, for example, a chemical solution such as a mixture of ethyl lactate, anisole, methyl butyl acetate, amyl acetate, cresol novolak resin, and diazo photoactive compound (referred to as SPR9), or another stripping process. In another embodiment, the photoresist may be stripped using a mixture of a solvent (e.g., dimethyl sulfoxide (DMSO)), an alkaline (e.g., potassium hydroxide KOH or tetramethylammonium hydroxide (TMAH)), and a surfactant additive.

FIG. 5 further illustrates removal of exposed portions of the seed layer **208**. The removal process may be performed using, for example, a wet dip in a chemical solution of phosphoric acid (H_3PO_4) and hydrogen peroxide (H_2O_2), referred to as DPP, with 2% hydrofluoric (HF) acid, or another cleaning process, to remove exposed portions of the seed layer **208** and contaminants from the surface of the protective layer **106**.

FIG. 6 illustrates placement of one or more first integrated circuit dies **614** in accordance with an embodiment. The first integrated circuit dies **614** are bonded such that a backside of the integrated circuit dies **614**, e.g., a side opposite of the electrical contacts, is placed on the protective layer **106** using, for example a die attach film (DAF) **616** or other adhesive. The first integrated circuit dies **614** may be device dies comprising integrated circuit devices, such as transistors, capacitors, inductors, resistors (not shown), and the like, therein. Further, the first integrated circuit dies **614** may be logic dies, central processing unit (CPU) dies, memory dies, or the like. Furthermore, two first integrated circuit dies **614** are shown in FIG. 6 for illustrative purposes, and other embodiments may include fewer or more integrated circuit dies. Additionally, as explained in greater detail below, the structure being formed will be diced to form separate

packages, each package containing a single integrated circuit die. In other embodiments, however, each package may contain a plurality of integrated circuit dies.

Referring to FIG. 7, molding compound **716** (alternatively referred to as an encapsulating material) is molded onto integrated circuit dies **614** and through vias **412**. The top surface of molding compound **716** may be higher than, or level with, top surfaces of the first integrated circuit dies **614** and/or the through vias **412**. In embodiments in which the molding compound **716** is formed to a height greater than the through vias **412**, a thinning process may be performed to expose the through vias **412** through the molding compound **716**, thereby achieving a result similar to that illustrated in FIG. 7, thereby allowing electrical connections to be made to the through vias such as discussed in greater detail below. The thinning process may employ a mechanical grinding process, a chemical polishing process, an etching process, combinations thereof, or the like.

The through vias **412** may extend above the first integrated circuit dies **614**, and accordingly, the through vias **412** and the molding compound **716** may be further reduced such that electrical contact may be made to the first integrated circuit dies **614**. The through vias **412** may be reduced by grinding, etching, or another suitable method.

Optionally, a cleaning process may be performed. The above grinding process may result in a grinding residue remaining on the through vias **412**. The cleaning process removes or reduces this grinding residue, thereby allowing better electrical contact to be formed to the through vias **412**. The cleaning process, which may result in a recess, may be a wet etch process using, for example, KOH, formic acid, H_2SO_4 , a mixture of HF and HNO_3 , a mixture of $HClO_4$ and H_3COOH , or a solution of phosphoric acid (H_3PO_4) and hydrogen peroxide (H_2O_2) mixture.

Next, as shown in FIG. 8, one or more redistribution layers (RDLs), one RDL **818** being shown, is formed to provide electrical connections to and/or between the through vias **412** and the first integrated circuit dies **614** in accordance with an embodiment. The RDL **818** may comprise a layer of a dielectric layer (e.g., a passivation layer) having a conductive layer formed therein. The dielectric layer may comprise, for example, a polymer material, such as epoxy, polyimide, polybenzoxazole (PBO), and the like, or may be formed of commonly known dielectric materials, such as spin-on glass, silicon oxide, silicon oxynitride, or the like, formed by any suitable method such as spin coating. The conductive line may be formed of, for example, a metal, such as Cu, Ag, Al, Ni, combinations thereof, or the like.

Also shown in FIG. 8 are a first set of electrical connectors **820** formed along a surface of the RDL **818**. Electrical connectors **820** may be solder balls, metal pads, metal pillars, and/or combinations thereof, and may be formed of gold, silver, nickel, tungsten, aluminum, and/or alloys thereof. Optionally, an under-bump metallurgy (UBM) structure may be formed on the RDL **818** prior to forming the first set of electrical connectors **820**. Generally, the UBM structure comprises a conductive pad formed upon the RDL and upon which the first set of electrical connectors are placed.

FIG. 9 illustrates the structure of FIG. 8 bonded to a carrier structure, such as a carrier tape **922**, after the debonding from the carrier substrate **102** in accordance with an embodiment. In an embodiment, the carrier tape **922** has an adhesive surface that is used to attach the electrical connectors **820** to the carrier tape **922**. The carrier substrate **102** is de-bonded. In an embodiment in which the adhesive layer **104** is formed of a light-sensitive adhesive, the carrier

5

substrate **102** may be de-bonded by, for example, exposing the adhesive layer **104** to a UV light or a laser, causing it to lose its adhesive property.

Thereafter, as illustrated in FIG. **10**, contact pad openings **1024** may be formed through the protective layer **106** in accordance with an embodiment. The contact pad openings **1024** expose portions of the underlying through vias **412**. In subsequent processing, the contact pad openings **1024** allow electrical contact to be made to respective ones of the through vias **412**. For example, as discussed below, a semiconductor package having one or more integrated circuit dies **614** may be mounted over the protective layer **106**, making electrical contact to the through vias **412** through the contact pad openings **1024**. Optionally, a UBM structure may be formed on the exposed portions of the through vias **412** prior to forming the electrical connectors **820**.

The contact pad openings **1024** may be formed using etching or laser drilling techniques. For example photolithography techniques may be used to deposit and pattern a mask over the protective layer **106**. Thereafter, a dry or wet etch process may be used to form the openings and the mask may be removed.

Optionally, the through vias **412** may be recessed using an etch process to remove the seed layer **208** and/or portions of the through vias **412**. It is believed that recessing or removing the seed layer **208** allows a better electrical connection as well as providing more of an indentation into which a solder ball may be placed as explained below. Furthermore, the recesses in the seed layer **208** and/or the through vias **412** may provide more structure support and reduce die shift. The etch process may be wet or dry etch process, such as a gas mixture of CF_4 , O_2 , and Ar, a chemical solution of phosphoric acid (H_3PO_4) and hydrogen peroxide (H_2O_2), referred to as DPP, or 2% hydrofluoric (HF) acid.

FIG. **11** illustrates results of a dicing process and a stacking of multiple integrated circuit packages in accordance with an embodiment. A first integrated circuit package **1126** is formed from the dicing process performed on the structure illustrated in FIG. **10**. A second integrated circuit package **1128** is bonded on the first integrated circuit package **1126**. The second integrated circuit package **1128** comprises, for example, two integrated circuit dies **1130** wire bonded onto a packaging substrate **1132**. The second integrated circuit package **1128** is electrically coupled to the through vias **412** using, for example, a second set of electrical connectors **1134**. The second set of electrical connectors **1134** may be solder balls, metal pads, metal pillars, and/or combinations thereof, and may be formed of gold, silver, nickel, tungsten, aluminum, and/or alloys thereof.

Optionally, an underfill **1136** may be placed between the first integrated circuit package **1126** and the second integrated circuit package **1128**. The underfill material **1136** is dispensed between the first integrated circuit package **1126** and the second integrated circuit package **1128**. The underfill material **1136** may be a liquid epoxy, deformable gel, silicon rubber, a combination thereof, and/or the like dispensed using acceptable dispensing equipment.

FIGS. **12-18** illustrate another embodiment of forming a PoP structure. The reference numerals utilized in FIGS. **12-18** are the same as similar layers/structures as those used in FIGS. **1-11**. As such, layers and structures having the same reference numerals may be formed using similar materials and methods as those discussed above with reference to FIGS. **1-11** and will not be repeated. The following discussion provides a brief overview of the process flow of the second embodiment.

6

FIG. **12** illustrates a formation of the adhesive layer **104** over the carrier substrate **102**. The seed layer **208** is formed over the adhesive layer **104**, and the protective layer **106** is formed over the seed layer **208**. Also illustrated in FIG. **12** is the patterned mask **310** over the protective layer **106**. The patterned mask **310** is patterned to form the through vias **412** as illustrated in FIG. **13**. In this embodiment, the protective layer **106** is patterned using the patterned mask **310** prior to forming the through vias **412**.

FIG. **14** illustrates removal of the patterned mask **310** and placement of the first integrated circuit dies **614**. FIG. **15** illustrates formation and grinding (if necessary) of the molding compound **716**, formation of one or more RDLs **818**, and placement of the electrical connectors **820**.

Thereafter, FIG. **16** illustrates attaching the structure to a carrier structure, such as the carrier tape **922**, debonding the carrier substrate **102**. The seed layer **208** is removed in FIG. **17**. The seed layer **208** may be removed, for example, by grinding, etching, combinations thereof, or the like. The final structure is illustrated in FIG. **18** after singulation and attachment of the second integrated circuit package **1128**.

The embodiment illustrated in FIGS. **12-18** differ from the embodiment illustrated in FIGS. **1-11** in at least the formation of the seed layer **208** and the protective layer **106**. In particular, the embodiment illustrated in FIGS. **1-11** form the protective layer **106** first and the seed layer **208** is formed on top of the protective layer **106**. In contrast, the embodiment illustrated in FIGS. **12-18** form the seed layer **208** first and the protective layer **106** is formed over the seed layer **208**. As a result of this change in the ordering, the seed layer **208** in the second embodiment is not patterned using the through vias **412** as a mask as illustrated in FIG. **5** of the first embodiment. Instead, the seed layer **208** remains until after the debond process is performed as illustrated in FIG. **16**. The resulting package exhibits a protective layer, e.g., a PBO layer, extending over the top of the bottom die and extending partially along a sidewall of the through vias **412**.

In comparison, the embodiment illustrated in FIGS. **1-11** have the protective layer **106** over the through vias, with openings formed in the protective layer **106** to form electrical contacts with the through vias **412**.

FIGS. **19-22** illustrate yet another embodiment of forming a PoP structure. The reference numerals utilized in FIGS. **19-22** are the same as similar layers/structures as those used in FIGS. **1-11**. As such, layers and structures having the same reference numerals may be formed using similar materials and methods as those discussed above with reference to FIGS. **1-11** and will not be repeated. The following discussion provides a brief overview of the process flow of the third embodiment.

Referring first to FIG. **19**, the carrier substrate **102** has formed thereon the adhesive layer **104** and, optionally, the seed layer **208**. The patterned mask **310** has been formed and patterned, and the through vias **412** have been formed in openings of the patterned mask **310**. In this embodiment, the protective layer **106** is not formed on the carrier substrate **102**, rather, the protective layer **106** will be formed directly on the die as discussed below.

FIG. **20** illustrates removal of the patterned mask **310**. Exposed portions of the seed layer **208** may be etched, if present, using the through vias **412** as a mask, similar to the first embodiment. The first integrated circuit dies **614** may be placed. Molding compound **716** is formed (and ground if necessary), RDLs **818** are formed, and electrical connectors **820** are placed. In FIG. **21**, the carrier substrate **102** is

debonded. The final structure is illustrated in FIG. 22 after singulation and attachment of the second integrated circuit package 1128.

In yet another embodiment, processes similar to those discussed above may be utilized to form a package without through vias. For example, FIG. 23 illustrates an embodiment in which no through vias are utilized. The processes utilized above with reference to FIGS. 19-22 may be utilized, except steps regarding the optional seed layer and the second integrated circuit package are omitted. Embodiments such as this provide a protective layer, e.g., a PBO layer, over the backside of the integrated circuit die.

FIG. 24 is a flow chart of a process that may be used as described above with reference to FIGS. 1-11. The process begins in step 2402, wherein an adhesive layer and a protective layer are formed on a carrier substrate, as discussed above with reference to FIG. 1. Next, in step 2404, a seed layer is formed over the protective layer, as discussed above with reference to FIG. 2. In step 2406, a patterned mask is deposited and patterned to form openings, which are filled with a conductive material to form through vias, as discussed above with reference to FIGS. 3 and 4. Next, in step 2408, the patterned mask is removed and exposed portions of the seed layer are removed as discussed above with reference to FIG. 5. Dies are attached and a molding compound is formed, as discussed above with reference to FIGS. 6 and 7, in step 2410. In step 2412, RDLs are formed and solder balls are attached as discussed above with reference to FIG. 8. In step 2414, the structure is attached to a carrier tape, the carrier substrate is debonded, and the protective layer is patterned, as discussed above with reference to FIGS. 9 and 10. Finally, in step 2416, a singulation process is performed and a second package is attached to the first package formed above as discussed above with reference to FIG. 11.

FIG. 25 is a flow chart of a process that may be used as described above with reference to FIGS. 12-18. The process begins in step 2502, wherein an adhesive layer, a seed layer, and a protective layer is formed over a carrier substrate as discussed above with reference to FIG. 12. A patterned mask is also formed and patterned to form openings. Next in step 2504, the openings in the patterned mask are filled with a conductive material to form through vias as discussed above with reference to FIG. 13. In step 2506, the patterned mask is removed and dies are attached, as discussed above with reference to FIG. 14. A molding compound and RDLs are formed and solder balls are attached in step 2508, as discussed above with reference to FIG. 15. Next, in step 2510, the structure is attached to a carrier tape, and the carrier substrate is debonded, as discussed above with reference to FIG. 16. In step 2512, excess material of the seed layer is removed as discussed above with reference to FIG. 17. Finally, in step 2514, a singulation process is performed to form a first package and a second package is formed on the first package as discussed above with reference to FIG. 18. An underfill material may be placed between the first and second packages.

FIG. 26 is a flow chart of a process that may be used as described above with reference to FIGS. 19-23. The process begins in step 2602, wherein an adhesive layer and an optional seed layer are formed on a carrier substrate. A mask is formed and patterned with openings, which are filled with a conductive material to form through vias, as discussed above with reference to FIG. 19. Next in step 2604, the patterned mask is removed and exposed portion of the seed layer, if present, are removed. A die with a protective layer attached to the surface of the die is attached to the carrier

substrate, and a molding compound and RDLs are formed. Additionally, solder balls are attached, as discussed above with reference to FIG. 20. In step 2606, the structure is attached to a carrier tape, and the carrier substrate is debonded, as discussed above with reference to FIG. 21. Finally, in step 2608, a singulation process is performed to form a first package and a second package is formed on the first package as discussed above with reference to FIG. 22, or optionally a singulation process is performed to form a first package without the through vias as discussed above with reference to FIG. 23. An underfill material may be placed between the first and second packages.

Embodiments such as those discussed above may achieve better warpage control, particularly with thin integrated fan-out (InFO) PoP designs by providing an opposite stress than the warpage induced by the RDL formation. Furthermore, because excess seed layer material is removed prior to forming the molding compound, the amount of metal grinding, which may clog the grinding equipment and cause roughened ground surfaces, is reduced. The protective layer and/or recesses formed in the through vias also may reduce die shift and solder ball cracking by providing additional lateral support.

In an embodiment, a method of forming a semiconductor device is provided. The method includes forming a protective layer over a carrier substrate and forming through vias extending up from the protective layer. One or more dies are attached to the protective layer, and a molding compound is placed between the through vias and the dies. Electrical connectors are placed on the through vias and electrical contacts on the dies. A debonding process removes the carrier wafer and the protective layer is exposed.

In another embodiment, a semiconductor device is provided. The semiconductor device includes a first package and a second package mounted on the first package. The first package includes one or more RDLs and an integrated circuit die on the RDLs. A molding compound is placed adjacent the sidewalls of the integrated circuit dies and through vias extend through the molding compound. A protective layer is over the integrated circuit dies.

In yet another embodiment, a method of forming a semiconductor device is provided. The method includes forming a seed layer over a carrier substrate and a protective layer over the seed layer, the protective layer having openings. Through vias are formed extending from the seed layer, the through vias extending through the openings of the protective layer. A die is attached to the protective layer, and a molding compound is formed between the through vias and the die. Electrical connectors are electrically coupled to the through vias and electrical contacts on the die. The carrier substrate is debonded, exposing the seed layer, and after the debonding, the seed layer is removed to expose the through vias.

In yet still another embodiment, a method of forming a semiconductor device is provided. The method includes forming a protective layer over a carrier substrate, the protective layer having an opening, and forming a through via in the opening of the protective layer. A die is attached to the protective layer, and a molding compound is formed between the through via and the die. Electrical connectors are electrically coupled to the through via and electrical contacts on the die, and after the electrically coupling, debonding the carrier substrate.

In yet still another embodiment, a semiconductor device is provided. The semiconductor device includes a first package, which further includes an integrated circuit die with a molding compound adjacent sidewalls of the inte-

grated circuit die. A protective layer extends over the integrated circuit die and the molding compound, and through vias extends through the molding compound and the protective layer.

Although the embodiments and their advantages have been described in detail, it should be understood that various changes, substitutions, and alterations can be made herein without departing from the spirit and scope of the embodiments as defined by the appended claims. Moreover, the scope of the present application is not intended to be limited to the particular embodiments of the process, machine, manufacture, and composition of matter, means, methods and steps described in the specification. As one of ordinary skill in the art will readily appreciate from the disclosure, processes, machines, manufacture, compositions of matter, means, methods, or steps, presently existing or later to be developed, that perform substantially the same function or achieve substantially the same result as the corresponding embodiments described herein may be utilized according to the disclosure. Accordingly, the appended claims are intended to include within their scope such processes, machines, manufacture, compositions of matter, means, methods, or steps. In addition, each claim constitutes a separate embodiment, and the combination of various claims and embodiments are within the scope of the disclosure.

What is claimed is:

1. A semiconductor device comprising:
 an integrated circuit die, the integrated circuit die having an active side and a backside, the active side having electrical contacts;
 a protective layer over a backside of the integrated circuit die;
 a die-attach film interposed between the protective layer and the integrated circuit die;
 a molding compound adjacent opposing sidewalls of the integrated circuit die, opposing sidewalls of the die-attach film, and opposing sidewalls of the protective layer; and
 conductors extending through the molding compound.
2. The semiconductor device of claim 1, wherein a surface of the conductors are level with a surface of the protective layer.
3. The semiconductor device of claim 1, wherein each of the conductors comprises a seed layer and a through via overlying the seed layer.
4. The semiconductor device of claim 3, further comprising an electrical connection coupled to the seed layer, wherein the seed layer is interposed between the through via and the electrical connection.
5. The semiconductor device of claim 4, further comprising:
 a package bonded to the electrical connection; and
 an underfill extending from the protective layer to the package.
6. The semiconductor device of claim 1, further comprising one or more redistribution layers over the molding compound and the integrated circuit die.
7. The semiconductor device of claim 6, wherein integrated circuit die is interposed between the one or more redistribution layers and the protective layer.

8. A semiconductor device comprising:
 an integrated circuit die;
 a molding compound adjacent sidewalls of the integrated circuit die;
 a protective layer over the integrated circuit die and the molding compound, the protective layer being in direct contact with the molding compound; and
 conductors extending through the molding compound and the protective layer, the conductors comprising a single continuous material in the molding compound and the protective layer, a surface of the conductors being level with a surface of the protective layer.
9. The semiconductor device of claim 8, further comprising a die-attach film interposed between the integrated circuit die and the protective layer.
10. The semiconductor device of claim 8, further comprising:
 a package; and
 first electrical connectors electrically coupling the package to the conductors.
11. The semiconductor device of claim 10, further comprising one or more redistribution layers along a surface of the integrated circuit die and the molding compound, wherein the conductors and portions of the one or more redistribution layers are electrically interposed between the package and the integrated circuit die.
12. The semiconductor device of claim 11, further comprising second electrical connectors electrically coupled to the one or more redistribution layers, wherein the one or more redistribution layers are interposed between the second electrical connectors and the integrated circuit die.
13. The semiconductor device of claim 10, wherein the first electrical connectors comprise solder.
14. The semiconductor device of claim 8, wherein sidewalls of the protective layer are free of the molding compound.
15. A semiconductor device comprising:
 an integrated circuit die, the integrated circuit die having an active side and a backside, the active side having electrical contacts;
 a molding compound adjacent sidewalls of the integrated circuit die;
 a protective layer over a backside of the integrated circuit die, the protective layer extending along a surface of the molding compound;
 through vias extending through the molding compound;
 a package electrically coupled to the through vias by electrical connectors; and
 underfill interposed between the protective layer and the package.
16. The semiconductor device of claim 15, wherein the through vias extend through the protective layer.
17. The semiconductor device of claim 15, wherein the through vias comprise a seed layer and a conductive layer.
18. The semiconductor device of claim 17, wherein a surface of the seed layer is level with a surface of the molding compound.
19. The semiconductor device of claim 15, further comprising solder coupled to the through vias.
20. The semiconductor device of claim 19, wherein the solder extends through the protective layer.
